

The oversight layer for autonomous agents paying over x402.
See every payment. Bound it. Stop it. Without ever holding a key.

THE GAP

The rail is solved.
The oversight isn't.

x402 lets an agent settle value on its own — pay per call for data, inference, RPC, signals. Coinbase, the x402 Foundation, and the Solana facilitators have made the rail work. The piece still missing is the thing a human keeps next to the agent: a live view of what it's spending, a policy it can't exceed, and a switch that stops it.

Across the agentic-commerce stack, identity, trust, and spend-control is where the runaway-spend and fraud risk concentrates — and it's the gap between an x402 demo and an x402 deployment.

WHAT IT DOES

SEE IT

A live tape of every 402 → clear → sign → settle, with running spend, per-merchant breakdown, latency, and the settlement signature linked to the explorer.

BOUND IT

Per-call and daily USD caps plus a merchant allowlist — evaluated and enforced before the agent signs.

STOP IT

One kill-switch that denies all clearance instantly. The human's hand stays on the off switch.

HOW IT FITS — OUT OF THE PAYMENT PATH

- 1. agent gets 402 payment required
- 2. agent asks monitor → clear this pay? (caps · allowlist · halt)
- 3. if cleared → agent signs + settles on Solana
- 4. agent reports each phase → live tape + spend + flags
- ↳ over-cap / halted → BLOCKED before any signature

The monitor is read-only and never holds keys or signs. If it's down, payments still settle — you just lose oversight. So adding x402-watch never makes the rail less reliable. The honest failure mode for an observability layer.

WHY IT MATTERS FOR X402

SPEND-CONTROL IS THE ADOPTION UNLOCK

An agent with a funded wallet and an x402 client can spend with no human in the loop — that's the point, and the exposure. x402-watch makes that supervisable without slowing the agent, so teams can let agents transact at higher value and volume. Safety isn't a tax on the rail; it's what takes x402 from demo to production.

BUILT ON SOLANA

Real mode settles USDC on Solana through a facilitator via @x402/fetch · @x402/svm · @x402/express — sub-cent fees, ~400ms finality. The demo runs simulated settlement so it's always live; the trust layer (clearance, caps, flags, halt) is fully real.

THE ASK — TO THE X402 TEAM

WHERE YOU COME IN

- Feedback on the spend-control model & the SDK surface we wired against
- Ecosystem listing so agent builders find the off-switch
- Make x402-watch a reference oversight integration for x402 on Solana
- Reference-integration grant or design partnership
